

DATA STRUCTURES AND ALGORITHMS

LECTURE 4

Lect. PhD. Onet-Marian Zsuzsanna

Babeş - Bolyai University
Computer Science and Mathematics Faculty

2024 - 2025

- Containers

- ADT Bag and ADT SortedBag
- ADT Set and ADT SortedSet
- ADT Matrix
- ADT Map and ADT SortedMap
- ADT MultiMap and SortedMultiMap
- ADT Stack
- ADT Queue

- As discussed in Lecture 3, for sorted containers we assume that there is a general *relation* that is used for comparison/sorting.
- From your feedback I had the feeling that this relation is not very clear to you (neither what it actually is and nor how it will look like in C++ for your labs) so I prepared a small example (C++ code). You can find it on Teams.

- Containers
- Linked Lists

Source: <https://www.vectorstock.com/royalty-free-vector/patients-in-doctors-waiting-room-at-the-hospital-vector-12041494>

- Consider the following queue in front of the Emergency Room.
Who should be the next person checked by the doctor?

ADT Priority Queue

- The ADT Priority Queue is a container in which each element has an associated *priority* (of type *TPriority*).
- In a Priority Queue access to the elements is restricted: we can access only the element with the highest priority.
- Because of this restricted access, we say that the Priority Queue works based on a **HPF - Highest Priority First** policy.

- In order to work in a more general manner, we can define a relation \mathcal{R} on the set of priorities: $\mathcal{R} : TPriority \times TPriority$
- When we say *the element with the highest priority* we will mean that the highest priority is determined using this relation \mathcal{R} .
- If the relation $\mathcal{R} = " \geq "$, the element with the *highest priority* is the one for which the value of the priority is the largest (maximum).
- Similarly, if the relation $\mathcal{R} = " \leq "$, the element with the *highest priority* is the one for which the value of the priority is the lowest (minimum).

- The domain of the ADT Priority Queue:
 $\mathcal{PQ} = \{pq | pq \text{ is a priority queue with elements } (e, p), e \in TElement, p \in TPriority\}$
- The interface of the ADT Priority Queue contains the following operations:

Priority Queue - Interface II

- **init** (pq , R)
 - **descr:** creates a new empty priority queue
 - **pre:** R is a relation over the priorities,
 $R : TPriority \times TPriority$
 - **post:** $pq \in \mathcal{PQ}$, pq is an empty priority queue

Priority Queue - Interface III

- **destroy(pq)**
 - **descr:** destroys a priority queue
 - **pre:** $pq \in \mathcal{PQ}$
 - **post:** pq was destroyed

Priority Queue - Interface IV

- $\text{push}(pq, e, p)$
 - **descr:** pushes (adds) a new element to the priority queue
 - **pre:** $pq \in \mathcal{PQ}, e \in TElm, p \in TPriority$
 - **post:** $pq' \in \mathcal{PQ}, pq' = pq \oplus (e, p)$

- **pop (pq)**
 - **descr:** pops (removes) from the priority queue the element with the highest priority. It returns both the element and its priority
 - **pre:** $pq \in \mathcal{PQ}$, pq is not empty
 - **post:** $pop \leftarrow (e, p)$, $e \in TElem$, $p \in TPriority$, e is the element with the highest priority from pq , p is its priority.
 $pq' \in \mathcal{PQ}$, $pq' = pq \ominus (e, p)$
 - **throws:** an exception if the priority queue is empty.

- **top (pq)**

- **descr:** returns from the priority queue the element with the highest priority and its priority. It does not modify the priority queue.
- **pre:** $pq \in \mathcal{PQ}$, pq is not empty
- **post:** $top \leftarrow (e, p)$, $e \in TElement$, $p \in TPriority$, e is the element with the highest priority from pq , p is its priority.
- **throws:** an exception if the priority queue is empty.

Priority Queue - Interface VII

- **isEmpty(pq)**

- **Description:** checks if the priority queue is empty (it has no elements)
- **Pre:** $pq \in \mathcal{PQ}$
- **Post:**

$$isEmpty \leftarrow \begin{cases} \text{true, if } pq \text{ has no elements} \\ \text{false, otherwise} \end{cases}$$

Priority Queue - Interface VIII

- **Note:** priority queues cannot be iterated, so they don't have an *iterator* operation!

- The ADT Deque (Double Ended Queue) is a container in which we can insert and delete from both ends:
 - We have *push_front* and *push_back*
 - We have *pop_front* and *pop_back*
 - We have *top_front* and *top_back*
 - And obviously, *init* and *isEmpty*.
- **Note:** Specifications for these operations are similar to the specifications of the corresponding operations for the *stack* and *Queue*
- We can simulate both stacks and queues with a deque if we restrict ourselves to using only part of the operations.

- A *list* can be seen as a sequence of elements of the same type, $\langle l_1, l_2, \dots, l_n \rangle$, where there is an order of the elements, and each element has a *position* inside the list.
- In a list, the order of the elements is important (positions are important).
- The number of elements from a list is called the length of the list. A list without elements is called *empty*.

- A List is a container which is either *empty* or
 - it has a unique *first* element
 - it has a unique *last* element
 - for every element (except for the last) there is a unique *successor* element
 - for every element (except for the first) there is a unique *predecessor* element
- In a list, we can insert elements (using positions), remove elements (using positions), we can access the successor and predecessor of an element from a given position, we can access an element from a position.

ADT List - Positions

- Every element from a list has a unique position in the list:
 - positions are relative to the list (but important for the list)
 - the position of an element:
 - identifies the element from the list
 - determines the position of the successor and predecessor element (if they exist).

- Position of an element can be seen in different ways:
 - as the *rank* of the element in the list (first, second, third, etc.)
 - similarly to an array, the position of an element is actually its index
 - as a *reference* to the memory location where the element is stored.
 - for example a pointer to the memory location
- For a general treatment, we will consider in the following the *position* of an element in an abstract manner, and we will consider that positions are of type *TPosition*

- A position p will be considered *valid* if it denotes the position of an actual element from the list:
 - if p is a pointer to a memory location, p is valid if it is the address of an element from a list (not NIL or some other address that is not the address of any element)
 - if p is the rank of the element from the list, p is valid if it is between 1 and the number of elements.
- For an invalid position we will use the following notation: \perp

- Domain of the ADT List:

$\mathcal{L} = \{l \mid l \text{ is a list with elements of type } T\text{Elem, each having a unique position in } l \text{ of type } T\text{Position}\}$

- **init(l)**
 - **descr:** creates a new, empty list
 - **pre:** true
 - **post:** $l \in \mathcal{L}$, l is an empty list

- **first(l)**

- **descr:** returns the $TPosition$ of the first element
- **pre:** $l \in \mathcal{L}$
- **post:** $first \leftarrow p \in TPosition$

$$p = \begin{cases} \text{the position of the first element from } l & \text{if } l \neq \emptyset \\ \perp & \text{otherwise} \end{cases}$$

- **last(l)**

- **descr:** returns the $TPosition$ of the last element

- **pre:** $l \in \mathcal{L}$

- **post:** $last \leftarrow p \in TPosition$

$$p = \begin{cases} \text{the position of the last element from } l & \text{if } l \neq \emptyset \\ \perp & \text{otherwise} \end{cases}$$

- **valid(l, p)**

- **descr:** checks whether a TPosition is valid in a list

- **pre:** $l \in \mathcal{L}, p \in TPosition$

- **post:** $valid \leftarrow \begin{cases} true & \text{if } p \text{ is a valid position in } l \\ false & \text{otherwise} \end{cases}$

- **next(l, p)**

- **descr:** goes to the next TPosition from a list
- **pre:** $l \in \mathcal{L}, p \in TPosition, valid(l, p)$
- **post:**

$$next \leftarrow q \in TPosition$$

$$q = \begin{cases} \text{the position of the next element after } p & \text{if } p \text{ is not the last position} \\ \perp & \text{otherwise} \end{cases}$$

- **throws:** exception if p is not valid

- $\text{previous}(l, p)$

- **descr:** goes to the previous TPosition from a list
- **pre:** $l \in \mathcal{L}, p \in \text{TPosition}, \text{valid}(l, p)$
- **post:**

$$\text{previous} \leftarrow q \in \text{TPosition}$$

$$q = \begin{cases} \text{the position of the element before } p & \text{if } p \text{ is not the first position} \\ \perp & \text{otherwise} \end{cases}$$

- **throws:** exception if p is not valid

- **getElement(l, p)**

- **descr:** returns the element from a given TPosition
- **pre:** $l \in \mathcal{L}, p \in TPosition, valid(l, p)$
- **post:** $getElement \leftarrow e, e \in TElem, e = \text{the element from position } p \text{ from } l$
- **throws:** exception if p is not valid

- **position(l, e)**

- **descr:** returns the TPosition of an element
- **pre:** $l \in \mathcal{L}, e \in TElem$
- **post:**

$$position \leftarrow p \in TPosition$$

$$p = \begin{cases} \text{the first position of element } e \text{ from } l & \text{if } e \in l \\ \perp & \text{otherwise} \end{cases}$$

- **setElement(l, p, e)**
 - **descr:** replaces an element from a TPosition with another
 - **pre:** $l \in \mathcal{L}, p \in TPosition, e \in TElem, valid(l, p)$
 - **post:** $l' \in \mathcal{L}$, the element from position p from l' is e ,
 $setElement \leftarrow el, el \in TElem, el$ is the element from position p from l (returns the previous value from the position)
 - **throws:** exception if p is not valid

- **addToBeginning(l, e)**
 - **descr:** adds a new element to the beginning of a list
 - **pre:** $l \in \mathcal{L}, e \in TElm$
 - **post:** $l' \in \mathcal{L}$, l' is the result after the element e was added at the beginning of l

- **addToEnd(l, e)**

- **descr:** adds a new element to the end of a list
- **pre:** $l \in \mathcal{L}, e \in TElem$
- **post:** $l' \in \mathcal{L}$, l' is the result after the element e was added at the end of l

- `addBeforePosition(l, p, e)`
 - **descr:** inserts a new element before a given position (which means that the new element will be on that position)
 - **pre:** $l \in \mathcal{L}, p \in TPosition, e \in TElem, valid(l, p)$
 - **post:** $l' \in \mathcal{L}, l'$ is the result after the element e was added in l before the position p
 - **throws:** exception if p is not valid

- **addAfterPosition(l, p, e)**

- **descr:** inserts a new element after a given position
- **pre:** $l \in \mathcal{L}, p \in TPosition, e \in TElem, valid(l, p)$
- **post:** $l' \in \mathcal{L}$, l' is the result after the element e was added in l after the position p
- **throws:** exception if p is not valid

- **remove(l, p)**
 - **descr:** removes an element from a given position from a list
 - **pre:** $l \in \mathcal{L}, p \in TPosition, valid(l, p)$
 - **post:** $remove \leftarrow e, e \in TElem, e$ is the element from position p from $l, l' \in \mathcal{L}, l' = l - e.$
 - **throws:** exception if p is not valid

- remove(l, e)

- descr:** removes the first occurrence of a given element from a list
- pre:** $l \in \mathcal{L}, e \in TElm$
- post:**

$$remove \leftarrow \begin{cases} \text{true} & \text{if } e \in l \text{ and it was removed} \\ \text{false} & \text{otherwise} \end{cases}$$

- **search(l, e)**

- **descr:** searches for an element in the list
- **pre:** $l \in \mathcal{L}, e \in TElm$
- **post:**

$$search \leftarrow \begin{cases} true & \text{if } e \in l \\ false & \text{otherwise} \end{cases}$$

- **isEmpty(l)**

- **descr:** checks if a list is empty
- **pre:** $l \in \mathcal{L}$
- **post:**

$$isEmpty \leftarrow \begin{cases} true & \text{if } l = \emptyset \\ false & \text{otherwise} \end{cases}$$

- **size(l)**
 - **descr:** returns the number of elements from a list
 - **pre:** $l \in \mathcal{L}$
 - **post:** $\text{size} \leftarrow$ the number of elements from l

- **destroy(l)**
 - **descr:** destroys a list
 - **pre:** $l \in \mathcal{L}$
 - **post:** l was destroyed

- **iterator(l , it)**
 - **descr:** returns an iterator for a list
 - **pre:** $l \in \mathcal{L}$
 - **post:** $it \in \mathcal{I}$, it is an iterator over l , the current element from it is the first element from l , or, if l is empty, it is invalid

- In Python and Java, TPosition is represented by an index.
- We can add and remove using index and we can access elements using their index (but we have iterator as well for the List).

- For example (Python):

```
insert (int index, E object)  
index (E object)
```

- Returns an integer value, position of the element (or exception if *object* is not in the list)

- For example (Java):

```
void add(int index, E element)  
E get(int index)  
E remove(int index)
```

- Returns the removed element

- If we consider that TPosition is an Integer value (similar to Python and Java), we can have an *IndexedList*
- In case of an *IndexedList* the operations that work with a position take as parameter integer numbers representing these positions
- There are less operations in the interface of the *IndexedList*
 - Operations *first*, *last*, *next*, *previous*, *valid* do not exist

- **init(I)**
 - **descr:** creates a new, empty list
 - **pre:** true
 - **post:** $I \in \mathcal{L}$, I is an empty list

- `getElement(l, i)`
 - **descr:** returns the element from a given position
 - **pre:** $l \in \mathcal{L}, i \in \mathcal{N}, i$ is a valid position
 - **post:** $getElement \leftarrow e, e \in TElm, e =$ the element from position i from l
 - **throws:** exception if i is not valid

- **position(l, e)**

- **descr:** returns the position of an element
- **pre:** $l \in \mathcal{L}, e \in TElm$
- **post:**

$$position \leftarrow i \in \mathbb{N}$$

$$i = \begin{cases} \text{the first position of element } e \text{ from } l & \text{if } e \in l \\ -1 & \text{otherwise} \end{cases}$$

- **setElement(l, i, e)**
 - **descr:** replaces an element from a position with another
 - **pre:** $l \in \mathcal{L}, i \in \mathcal{N}, e \in TElm$, i is a valid position
 - **post:** $l' \in \mathcal{L}$, the element from position i from l' is e ,
 $setElement \leftarrow el$, $el \in TElm$, el is the element from position i from l (returns the previous value from the position)
 - **throws:** exception if i is not valid

- **addToBeginning(l, e)**
 - **descr:** adds a new element to the beginning of a list
 - **pre:** $l \in \mathcal{L}, e \in TElm$
 - **post:** $l' \in \mathcal{L}$, l' is the result after the element e was added at the beginning of l

- **addToEnd(l, e)**
 - **descr:** adds a new element to the end of a list
 - **pre:** $l \in \mathcal{L}, e \in TElem$
 - **post:** $l' \in \mathcal{L}$, l' is the result after the element e was added at the end of l

- `addToPosition(l, i, e)`

- **descr:** inserts a new element at a given position (it is the same as *addBeforePosition*)
- **pre:** $l \in \mathcal{L}, i \in \mathcal{N}, e \in T\text{Elem}$, i is a valid position ($\text{size} + 1$ is valid for adding an element)
- **post:** $l' \in \mathcal{L}$, l' is the result after the element e was added in l at the position i
- **throws:** exception if i is not valid

- remove(l, i)

- descr:** removes an element from a given position from a list
- pre:** $l \in \mathcal{L}, i \in \mathcal{N}, i$ is a valid position
- post:** $remove \leftarrow e, e \in TElm, e$ is the element from position i from $l, l' \in \mathcal{L}, l' = l - e.$
- throws:** exception if i is not valid

- remove(l, e)

- descr:** removes the first occurrence of a given element from a list
- pre:** $l \in \mathcal{L}, e \in TElm$
- post:**

$$remove \leftarrow \begin{cases} \text{true} & \text{if } e \in l \text{ and it was removed} \\ \text{false} & \text{otherwise} \end{cases}$$

ADT IndexedList X

- $\text{search}(l, e)$
 - **descr:** searches for an element in the list
 - **pre:** $l \in \mathcal{L}, e \in TElm$
 - **post:**

$$\text{search} \leftarrow \begin{cases} \text{true} & \text{if } e \in l \\ \text{false} & \text{otherwise} \end{cases}$$

- **isEmpty(l)**
 - **descr:** checks if a list is empty
 - **pre:** $l \in \mathcal{L}$
 - **post:**

$$isEmpty \leftarrow \begin{cases} true & \text{if } l = \emptyset \\ false & \text{otherwise} \end{cases}$$

- **size(l)**
 - **descr:** returns the number of elements from a list
 - **pre:** $l \in \mathcal{L}$
 - **post:** $\text{size} \leftarrow$ the number of elements from l

- **destroy(l)**
 - **descr:** destroys a list
 - **pre:** $l \in \mathcal{L}$
 - **post:** l was destroyed

- **iterator(l , it)**
 - **descr:** returns an iterator for a list
 - **pre:** $l \in \mathcal{L}$
 - **post:** $it \in \mathcal{I}$, it is an iterator over l , the current element from it is the first element from l , or, if l is empty, it is invalid

- In STL (C++), TPosition is represented by an iterator.
- For example - vector:

`iterator insert(iterator position, const value_type& val)`

- Returns an iterator which points to the newly inserted element

`iterator erase (iterator position);`

- Returns an iterator which points to the element after the removed one

- For example - list:

`iterator insert(iterator position, const value_type& val)`

`iterator erase (iterator position);`

- If we consider that TPosition is an Iterator (similar to C++) we can have an *IteratedList*.
- In case of an *IteratedList* the operations that take as parameter a position use an Iterator (and the position is the current element from the Iterator)
- Operations *valid*, *next*, *previous* no longer exist in the interface of the List (they are operations for the Iterator).

- **init(l)**
 - **descr:** creates a new, empty list
 - **pre:** true
 - **post:** $l \in \mathcal{L}$, l is an empty list

- **first(I)**

- **descr:** returns an Iterator set to the first element
- **pre:** $I \in \mathcal{L}$
- **post:** $first \leftarrow it \in \text{Iterator}$

$$it = \begin{cases} \text{an iterator set to the first element} & \text{if } I \neq \emptyset \\ \text{an invalid iterator} & \text{otherwise} \end{cases}$$

- **last(l)**

- **descr:** returns an Iterator set to the last element

- **pre:** $l \in \mathcal{L}$

- **post:** $last \leftarrow it \in \text{Iterator}$

$$it = \begin{cases} \text{an iterator set to the last element} & \text{if } l \neq \emptyset \\ \text{an invalid iterator} & \text{otherwise} \end{cases}$$

- `getElement(l, it)`
 - **descr:** returns the element from the position denoted by an Iterator
 - **pre:** $l \in \mathcal{L}, it \in \text{Iterator}, valid(it)$
 - **post:** $getElement \leftarrow e, e \in TElm, e = \text{the element from } l \text{ from the current position}$
 - **throws:** exception if it is not valid

- $\text{position}(l, e)$
 - **descr:** returns an iterator set to the first position of an element
 - **pre:** $l \in \mathcal{L}, e \in T\text{Elem}$
 - **post:**

$$\text{position} \leftarrow it \in \text{Iterator}$$

$$it = \begin{cases} \text{an iterator set to the first position of element } e \text{ from } l & \text{if } e \in l \\ \text{an invalid iterator} & \text{otherwise} \end{cases}$$

- `setElement(l, it, e)`
 - **descr:** replaces the element from the position denoted by an Iterator with another element
 - **pre:** $l \in \mathcal{L}$, $it \in \text{Iterator}$, $e \in TElm$, $\text{valid}(it)$
 - **post:** $l' \in \mathcal{L}$, the element from the position denoted by it from l' is e , $\text{setElement} \leftarrow el$, $el \in TElm$, el is the element from the current position from it from l (returns the previous value from the position)
 - **throws:** exception if it is not valid

- **addToBeginning(l, e)**
 - **descr:** adds a new element to the beginning of a list
 - **pre:** $l \in \mathcal{L}, e \in TElm$
 - **post:** $l' \in \mathcal{L}$, l' is the result after the element e was added at the beginning of l

- **addToEnd(l, e)**
 - **descr:** inserts a new element at the end of a list
 - **pre:** $l \in \mathcal{L}, e \in TElm$
 - **post:** $l' \in \mathcal{L}$, l' is the result after the element e was added at the end of l

- `addToPosition(l, it, e)`
 - **descr:** inserts a new element at a given position specified by the iterator (it is the same as *addAfterPosition*)
 - **pre:** $l \in \mathcal{L}$, $it \in \text{Iterator}$, $e \in T\text{Elem}$, $\text{valid}(it)$
 - **post:** $l' \in \mathcal{L}$, l' is the result after the element e was added in l at the position specified by it
 - **throws:** exception if it is not valid

- `remove(l, it)`
 - **descr:** removes an element from a given position specified by the iterator from a list
 - **pre:** $l \in \mathcal{L}, it \in \text{Iterator}, valid(it)$
 - **post:** $remove \leftarrow e, e \in TElem, e$ is the element from the position from l denoted by $it, l' \in \mathcal{L}, l' = l - e.$
 - **throws:** exception if it is not valid

- remove(l, e)

- descr:** removes the first occurrence of a given element from a list
- pre:** $l \in \mathcal{L}, e \in TElm$
- post:**

$$remove \leftarrow \begin{cases} \text{true} & \text{if } e \in l \text{ and it was removed} \\ \text{false} & \text{otherwise} \end{cases}$$

- **search(l, e)**

- **descr:** searches for an element in the list
- **pre:** $l \in \mathcal{L}, e \in TElm$
- **post:**

$$search \leftarrow \begin{cases} \text{true} & \text{if } e \in l \\ \text{false} & \text{otherwise} \end{cases}$$

- **isEmpty(l)**
 - **descr:** checks if a list is empty
 - **pre:** $l \in \mathcal{L}$
 - **post:**

$$isEmpty \leftarrow \begin{cases} true & \text{if } l = \emptyset \\ false & \text{otherwise} \end{cases}$$

- **size(l)**
 - **descr:** returns the number of elements from a list
 - **pre:** $l \in \mathcal{L}$
 - **post:** $\text{size} \leftarrow$ the number of elements from l

- **destroy(l)**
 - **descr:** destroys a list
 - **pre:** $l \in \mathcal{L}$
 - **post:** l was destroyed

ADT SortedList

- We can define the ADT *SortedList*, in which the elements are memorized in an order given by a relation.
- You have below the list of operations for ADT *List*
 - init(l)
 - first(l)
 - last(l)
 - valid(l, p)
 - next(l, p)
 - previous(l, p)
 - getElement(l, p)
 - position(l, e)
 - setElement(l, p, e)
 - addToBeginning(l, e)
 - addToEnd(l, e)
 - addToPosition(l, p, e)
 - remove(l, p)
 - remove(l, e)
 - search(l, e)
 - isEmpty(l)
 - size(l)
 - destroy(l)

ADT SortedList

- The interface of the ADT *SortedList* is very similar to that of the ADT *List* with some exceptions:
 - The *init* function takes as parameter a relation that is going to be used to order the elements
 - We no longer have several *add* operations (*addToBeginning*, *addToEnd*, *addToPosition*), we have one single *add* operation, which takes as parameter only the element to be added (and adds it to the position where it should go based on the relation)
 - We no longer have a *setElement* operation (might violate ordering)
- We can consider *TPosition* in two different ways for a *SortedList* as well \Rightarrow *SortedIndexedList* and *SortedIteratedList*

Dynamic Array - review

- The main idea of the (dynamic) array is that all the elements from the array are in one single consecutive memory location.

Dynamic Array - review

- The main idea of the (dynamic) array is that all the elements from the array are in one single consecutive memory location.
- This gives us the main advantage of the array:
 - constant time access to any element from any position
 - constant time for operations (add, remove) at the end of the array

Dynamic Array - review

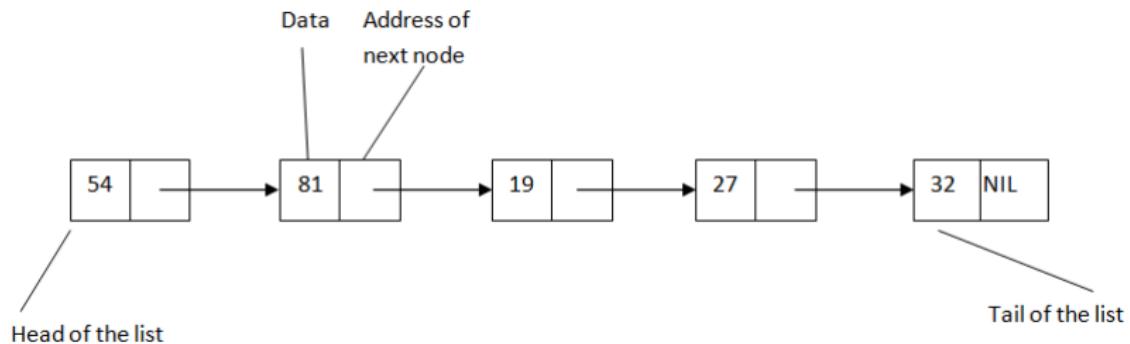

- The main idea of the (dynamic) array is that all the elements from the array are in one single consecutive memory location.
- This gives us the main advantage of the array:
 - constant time access to any element from any position
 - constant time for operations (add, remove) at the end of the array
- This gives us the main disadvantage of the array as well:
 - $\Theta(n)$ complexity for operations (add, remove) at the beginning of the array

- A *linked list* is a linear data structure, where the order of the elements is determined not by indexes, but by a pointer which is placed in each element.
- A linked list is a structure that consists of *nodes* (sometimes called *links*) and each node contains, besides the data (that we store in the linked list), a pointer to the address of the next node (and possibly a pointer to the address of the previous node).
- The nodes of a linked list are not necessarily adjacent in the memory, this is why we need to keep the address of the successor in each node.

- Elements from a linked list are accessed based on the pointers stored in the nodes.
- We can directly access only the first element (and maybe the last one) of the list.

Linked Lists

- Example of a linked list with 5 nodes:

Singly Linked Lists - SLL

- The linked list from the previous slide is actually a *singly linked list* - *SLL*.
- In a SLL each node from the list contains the data and the address of the next node.
- The first node of the list is called *head* of the list and the last node is called *tail* of the list.
- The tail of the list contains the special value *NIL* as the address of the next node (which does not exist).
- If the head of the SLL is *NIL*, the list is considered empty.

Singly Linked Lists - Representation

- For the representation of a SLL we need two structures: one structure for the node and one for the list itself.

SLLNode:

info: TElement //*the actual information*

next: ↑ SLLNode //*address of the next node*

Singly Linked Lists - Representation

- For the representation of a SLL we need two structures: one structure for the node and one for the list itself.

SLLNode:

info: TElement //*the actual information*

next: ↑ SLLNode //*address of the next node*

SLL:

head: ↑ SLLNode //*address of the first node*

- Usually, for a SLL, we only memorize the address of the head. However, there might be situations when we memorize the address of the tail as well (if it helps us implement the operations).

- Possible operations for a singly linked list:
 - search for an element with a given value
 - add an element (to the beginning, to the end, to a given position, after a given value)
 - delete an element (from the beginning, from the end, from a given position, with a given value)
 - get an element from a position
- These are *possible* operations; usually we need only part of them, depending on the container that we implement using a SLL.

function search (sll, elem) **is:**

//pre: *sll* is a SLL - singly linked list; *elem* is a TElem

//post: returns the node which contains *elem* as info, or NIL

function search (sll, elem) **is:**

//pre: sll is a SLL - singly linked list; elem is a TElem

//post: returns the node which contains elem as info, or NIL

current \leftarrow sll.head

while current \neq NIL **and** [current].info \neq elem **execute**

 current \leftarrow [current].next

end-while

search \leftarrow current

end-function

- Complexity:

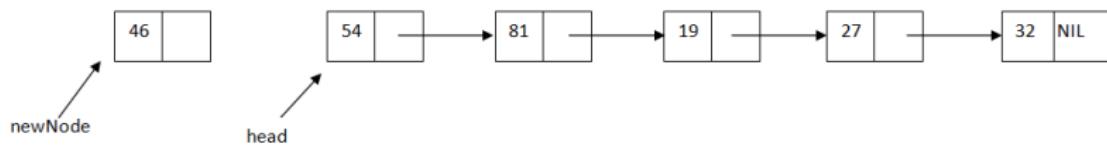

```
function search (sll, elem) is:
    //pre: sll is a SLL - singly linked list; elem is a TElem
    //post: returns the node which contains elem as info, or NIL
    current ← sll.head
    while current ≠ NIL and [current].info ≠ elem execute
        current ← [current].next
    end-while
    search ← current
end-function
```

- Complexity: $O(n)$ - we can find the element in the first node, or we may need to verify every node.

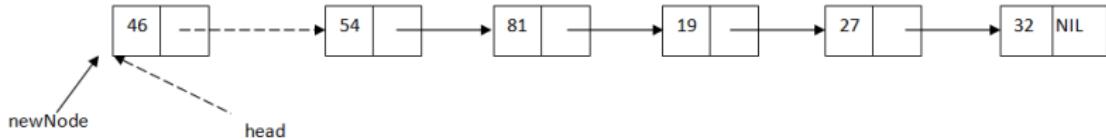

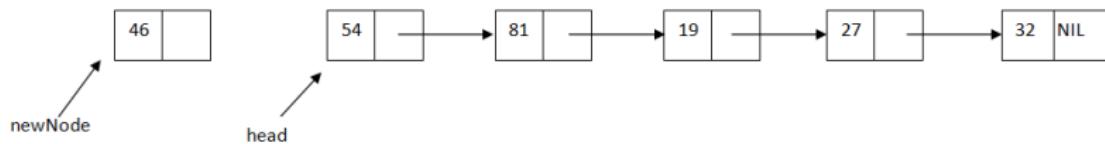

SLL - Walking through a linked list

- In the *search* function we have seen how we can walk through the elements of a linked list:
 - we need an auxiliary node (called *current*), which starts at the head of the list
 - at each step, the value of the *current* node becomes the address of the successor node (through the $\text{current} \leftarrow [\text{current}].\text{next}$ instruction)
 - we stop when the current node becomes *NIL*

SLL - Insert at the beginning

SLL - Insert at the beginning

subalgorithm insertFirst (sll, elem) **is:**

//pre: sll is a SLL; elem is a TElem

//post: the element elem will be inserted at the beginning of sll

newNode ← allocate() //allocate a new SLLNode

[newNode].info ← elem

[newNode].next ← sll.head

sll.head ← newNode

end-subalgorithm

- Complexity:

subalgorithm insertFirst (sll, elem) **is:**

//pre: sll is a SLL; elem is a TElem

//post: the element elem will be inserted at the beginning of sll

newNode ← allocate() //allocate a new SLLNode

[newNode].info ← elem

[newNode].next ← sll.head

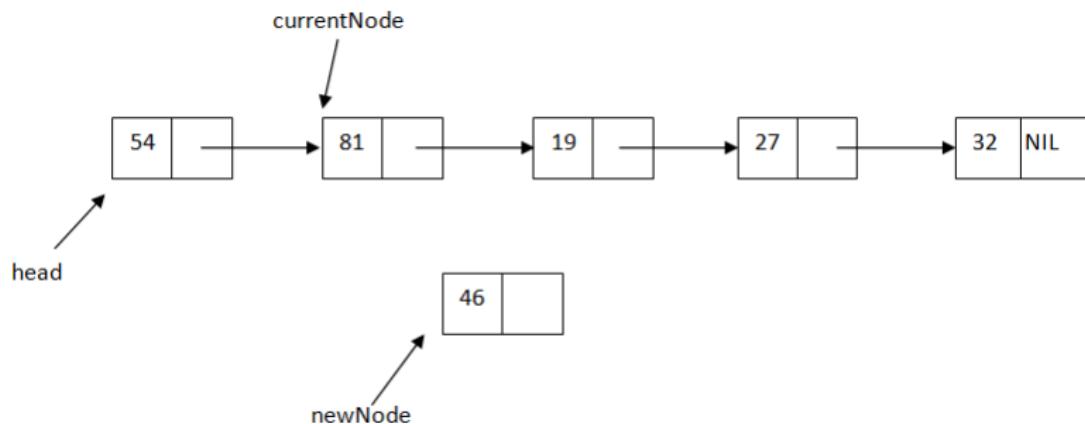

sll.head ← newNode

end-subalgorithm

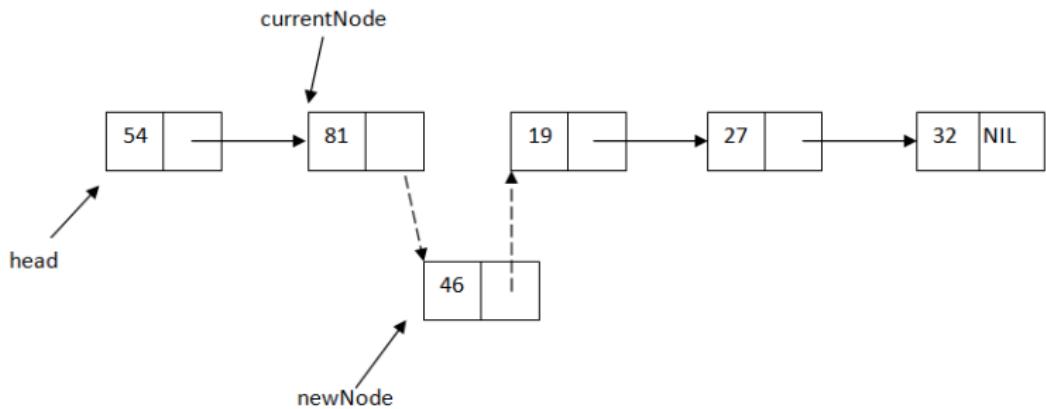

- Complexity: $\Theta(1)$

SLL - Insert after a node

- Suppose that we have the address of a node from the SLL (maybe because the search operation returned it) and we want to insert a new element after that node.

SLL - Insert after a node

SLL - Insert after a node

```
subalgorithm insertAfter(sll, currentNode, elem) is:
    //pre: sll is a SLL; currentNode is an SLLNode from sll;
    //elem is a TElem
    //post: a node with elem will be inserted after node currentNode
    newNode ← allocate() //allocate a new SLLNode
    [newNode].info ← elem
    [newNode].next ← [currentNode].next
    [currentNode].next ← newNode
end-subalgorithm
```

- Complexity:

SLL - Insert after a node

```
subalgorithm insertAfter(sll, currentNode, elem) is:
    //pre: sll is a SLL; currentNode is an SLLNode from sll;
    //elem is a TElem
    //post: a node with elem will be inserted after node currentNode
    newNode ← allocate() //allocate a new SLLNode
    [newNode].info ← elem
    [newNode].next ← [currentNode].next
    [currentNode].next ← newNode
end-subalgorithm
```

- Complexity: $\Theta(1)$

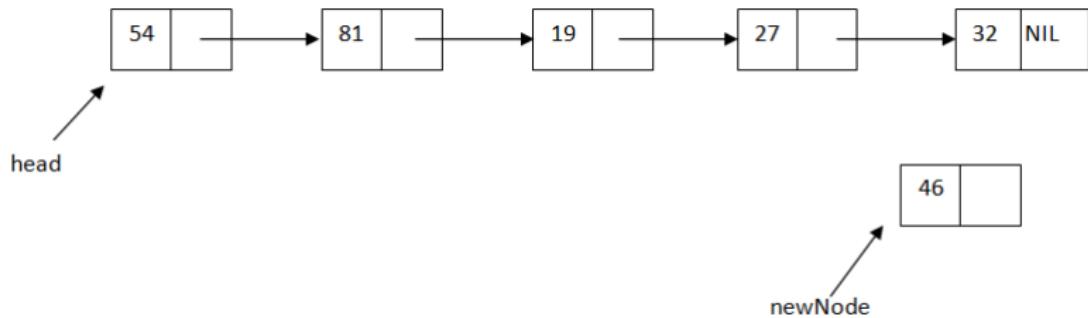

Insert before a node

- Think about the following case: if you have a node, how can you insert an element in front of the node?

- We usually do not have the node after which we want to insert an element: we either know the position to which we want to insert, or know the element (not the node) after which we want to insert an element.
- Suppose we want to insert a new element at integer position p (after insertion the new element will be at position p). Since we only have access to the *head* of the list we first need to find the position *after* which we insert the element.

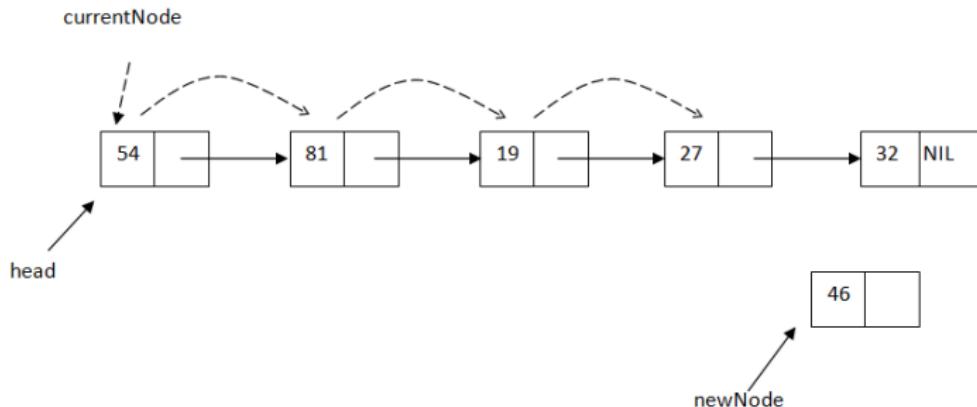

SLL - Insert at a position

- We want to insert element 46 at position 5.

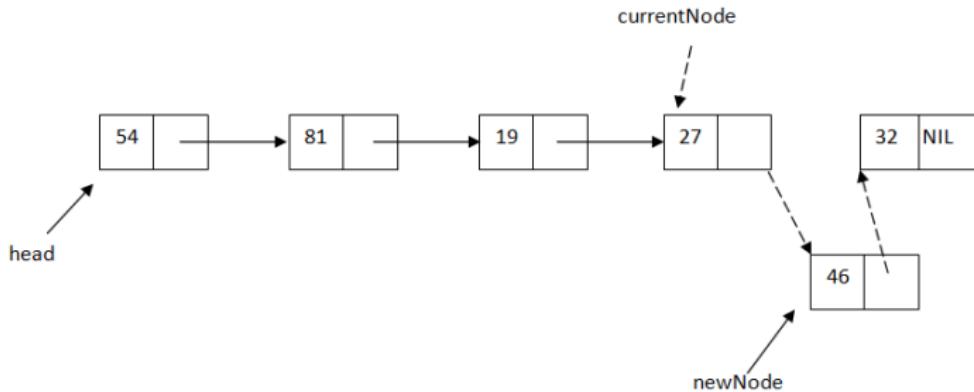

SLL - Insert at a position

- We need the 4th node (to insert element 46 after it), but we have direct access only to the first one, so we have to take an auxiliary node (*currentNode*) to get to the position.

SLL - Insert at a position

- Now we insert after node *currentNode*

SLL - Insert at a position

```
subalgorithm insertPosition(sll, pos, elem) is:
    //pre: sll is a SLL; pos is an integer number; elem is a TElem
    //post: a node with TElem will be inserted at position pos
    if pos < 1 then
        @error, invalid position
    else if pos = 1 then //we want to insert at the beginning
        newNode ← allocate() //allocate a new SLLNode
        [newNode].info ← elem
        [newNode].next ← sll.head
        sll.head ← newNode
    else
        currentNode ← sll.head
        currentPos ← 1
        while currentPos < pos - 1 and currentNode ≠ NIL execute
            currentNode ← [currentNode].next
            currentPos ← currentPos + 1
        end-while
    //continued on the next slide...
```

```
if currentNode ≠ NIL then
    newNode ← allocate() //allocate a new SLLNode
    [newNode].info ← elem
    [newNode].next ← [currentNode].next
    [currentNode].next ← newNode
else
    @error, invalid position
end-if
end-if
end-subalgorithm
```

- Complexity:

```
if currentNode ≠ NIL then
    newNode ← allocate() //allocate a new SLLNode
    [newNode].info ← elem
    [newNode].next ← [currentNode].next
    [currentNode].next ← newNode
else
    @error, invalid position
end-if
end-if
end-subalgorithm
```

- Complexity: $O(n)$

Get element from a given position

- Since we only have access to the head of the list, if we want to get an element from a position p we have to go through the list, node-by-node until we get to the p^{th} node.
- The process is similar to the first part of the *insertPosition* subalgorithm

SLL - Delete a given element

- How do we delete a given element from a SLL?

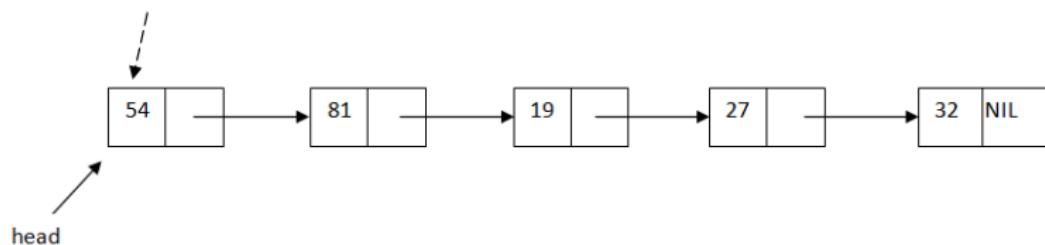

SLL - Delete a given element

- How do we delete a given element from a SLL?
- When we want to delete a node from the middle of the list (either a node with a given element, or a node from a position), we need to find the node *before* the one we want to delete.
- The simplest way to do this, is to walk through the list using two pointers: *currentNode* and *prevNode* (the node before *currentNode*). We will stop when *currentNode* points to the node we want to delete.

SLL - Delete a given element

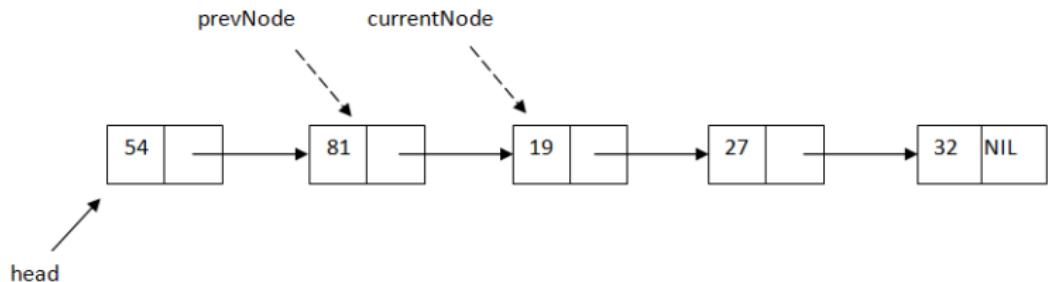

- Suppose we want to delete the node with information 19.

prevNode = NIL currentNode

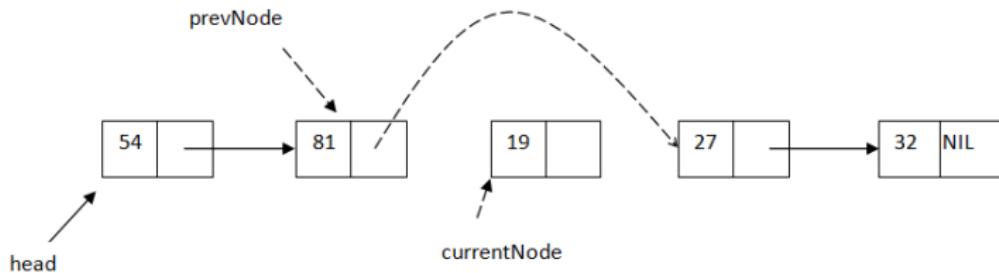

SLL - Delete a given element

- Move with the two pointers until *currentNode* is the node we want to delete.

SLL - Delete a given element

- Delete *currentNode* by *jumping over it*

SLL - Delete a given element

```
function deleteElement(sll, elem) is:  
    //pre: sll is a SLL, elem is a TElm  
    //post: the node with elem is removed from sll and returned  
    currentNode ← sll.head  
    prevNode ← NIL  
    while currentNode ≠ NIL and [currentNode].info ≠ elem execute  
        prevNode ← currentNode  
        currentNode ← [currentNode].next  
    end-while  
    if currentNode ≠ NIL AND prevNode = NIL then //we delete the head  
        sll.head ← [sll.head].next  
    else if currentNode ≠ NIL then  
        [prevNode].next ← [currentNode].next  
        [currentNode].next ← NIL  
    end-if  
    deleteElement ← currentNode  
end-function
```

- Complexity of *deleteElement* function:

SLL - Delete a given element

- Complexity of *deleteElement* function: $O(n)$

- Today we have talked about:
 - ADT Priority Queue
 - ADT Deque
 - ADT List (two versions: `IndexedList` and `IteratedList`)
 - Linked lists
 - Singly linked list
